

What happens when materials are mixed? – I

When different materials are mixed together a number of things may happen.

Liquid–liquid mix	Liquid–solid mix	Solid–solid mix
<p>Example 1: The liquids do not mix. They are <i>immiscible</i>. The more dense liquid sinks to the bottom and the less dense rises to the top.</p> <p>They do not react with each other. The two liquids can be separated by <i>siphoning</i>.</p> <p>Examples: olive oil and water</p> 	<p>Example 1: The solid does not dissolve. It is <i>insoluble</i> in the liquid.</p> <p>There is no chemical reaction between the two. The solid can be separated by <i>filtration</i>.</p> <p>Examples: vinegar and sawdust</p> 	<p>Example 1: If the solids have different-sized <i>particles</i>, they can be separated by <i>sieving</i>.</p> <p>Examples: flour and instant coffee grains</p> 
<p>Example 2: The liquids do mix because they have equal density. They are <i>miscible</i>.</p> <p>They do not react with each other. This is a <i>reversible</i> change. They can be separated by <i>distillation</i>.</p> <p>The liquids are heated until the lower boiling point of the two liquids is reached. This vapour is then collected in a condenser, where it returns to its liquid phase.</p> <p>Examples: water and fruit juice</p> 	<p>Example 2: The solid dissolves. It is <i>soluble</i> in the liquid.</p> <p>There is a chemical reaction between the two, resulting in a new substance being formed. The change is <i>irreversible</i>. The solid can not be separated from the liquid.</p> <p>Examples: vinegar and baking soda</p> 	<p>Example 2: The solids have same-sized particles and one dissolves in a liquid but the other does not. They can be separated by adding the liquid, filtering the insoluble solid and separating the soluble solid by evaporation.</p> <p>Examples: sand and sugar using water</p> 
<p>Example 3: The liquids do mix because they have equal density. They are <i>miscible</i>.</p> <p>The liquids react with each other to form another substance. This is an <i>irreversible</i> change because the liquids can not be separated.</p> <p>Examples: acid and alcohol</p> 	<p>Example 3: The solid dissolves. It is <i>soluble</i> in the liquid.</p> <p>There is no chemical reaction between the two. The change is <i>reversible</i>. The solid can be separated by <i>evaporation</i>.</p> <p>Examples: water and salt</p> 	<p>Example 3: The solids have same-sized particles and both dissolve in all liquids. They can not be separated easily.</p> <p>Examples: salt and caster sugar</p>
